Disclaimers

ZeeVee control offerings
ZeeVee provides modules/drivers for third-party control systems as a courtesy to our channel partners to speed development time. In addition to the modules/drivers, our fully documented ZyPer Management Platform API allows our customers to connect to nearly any control system.

ZeeVee support for control products
The ZeeVee support team is available to assist you in getting your new ZyPer encoders, decoders, and management system working correctly and providing direction with API calls for desired functionality.

ZeeVee limitation
Given the variety of capabilities across various control products, ZeeVee cannot commit to deep-rooted knowledge that would allow us to address all support requests. Further, the drivers provided may not include all commands needed for a particular solution that your organization has devised.

How you can prepare
While ZeeVee provides modules/drivers and the API, your organization will need expertise on the chosen control system and may require technical support from the control system vendor.

Where to find documentation
All ZeeVee and ZyPer documentation can be found on our website here: https://www.zeevee.com/documentation/.

The API for is fully documented in the ZyPer Management Platform User Manual, found here: https://www.zeevee.com/zyper_management_platform_user_manual

ZeeVee Control Modules/Drivers

ZeeVee provides many different control options for the ZyPer family of products. (ZyPer4K, ZyPerUHD, ZyPerHD). This includes the availability of modules or built in support directly for the following 3rd party control systems.

Support

Modules/Drivers for 3rd party control systems are provided as a courtesy to developers in an effort to reduce development time. They are provided “as-is” from ZeeVee with no additional support provided other than the accompanying documentation. See Disclaimers section at the beginning of this document.

Module/Driver Basics

A module or driver is an interface between the primary controller (Crestron, RTI, Control4 etc..) and the ZeeVee Management Platform (ZMP). Think of the module or driver as a translator. It will translate commands from the primary control system into the appropriate commands that can be understood by the ZyPerMP.

Note: Not all ZyPerMP API commands are supported by the module/driver. Our goal has been to support the most common and basic commands to allow routing of video from any source to any destination as well as some special features such as multiview and video walls.
Configuration Tips

Documentation

You will need to know the ZyPer Management Platform API commands to perform actions that are not provided by the module/driver. ZeeVee provides a fully open API for this purpose. Please download the ZyPer Management Platform User Guide from the following link:

https://www.zeevee.com/zyper_management_platform_user_manual/

API commands are listed in Chapter 3 of the manual. “Advanced Operation”

Basic Setup

Regardless of the control system used to control the ZyPer equipment, it is a requirement that the ZyPer Management Platform (ZMP) must be present.

1. The ZMP IP address should be configured either via DHCP or given a static address.
2. The ZMP IP address MUST be on the same network as the primary hardware controller.
   (Crestron 4-Series controller, Control4 EA1, EA3, EA5, DTVGameControl iPad)
3. All ZyPer endpoints should be configured using either the ZMP Graphical User Interface (GUI) or via the ZMP API (Telnet or SSH).
   a. Assign all endpoints a logical name (Encoders and Decoders)
   b. Design/create any video walls and give them logical names
   c. Design/create any multiview displays and give them logical names (ZyPer4K only)

Module/Driver Setup

Every control system is different but will have some common features when it comes to basic setup and configuration.

1. The IP address of the ZMP must be provided so that the primary controller can communicate with the ZMP.
a. Where the IP address is provided will vary based on the control system. Below are some examples

i. Crestron – SIMPL Windows under IP_Address field for the ZeeVee_ZyPerMP_Processor logic module. See image below:

![Image showing Crestron SIMPL Windows]

ii. Control4 – Composer, System Design-Properties tab, IP Address field.

2. The names of the endpoints must be provided. Similar to the IP address detailed above.

3. The names of Multiview’s (ZyPer4K only) need to be provided.
   a. Crestron – SIMPL Windows in the appropriate Multiview logic module.
   b. Control4 – Create a “virtual” encoder and assign it appropriate multiview name and set the “Input Join Type” to multiview.

**Important Crestron Note**

When using the Crestron module, the default join mode is “genlocked”. Be sure to change this to “fast-switched” if using the ZyPerHD or ZyPerUHD as the “genlocked” mode is not supported on these products.

You can change the default by editing the ZeeVee_ZyPer4K_Decoder_v1.0.1.usp file if desired.
Video Walls

Video walls are configured differently depending on the control system.

a. Crestron – Similar to IP address and multiview. SIMPL Windows in the appropriate Video Wall logic module.

b. Control4 – Video walls need to be assigned to a special programmed command. For example, a Red Button press on the SR260 remote control. In Composer highlight the room, select Programming and Commands. Select the “Red Button”. Then in the Actions window select ZeeVee ZyPer, scroll down to Device Specific Command. Enter the Encoder and Video Wall Names. (See image below)

RS232

The ZyPer Management Platform (ZMP) must first be linked to the specific endpoint to send RS232 information. This can be done with either the dataConnect or switch command.

Examples:
dataConnect Dec1 server rs232 tunnelPort 1234
switch Dec1 server rs232

**Note:** The feature of dataConnect was added to allow a third party to connect to the ZMP server with a specific port and pass raw or telnet API commands (depending on the mode) to the server and port which is designated for a particular encoder or decoder.

**Important Note:** Issuing the dataConnect or switch command can cause the ZyPer endpoint to reboot to enable the link. Disconnecting the link can also cause the endpoint to reboot. The link should only be established once and then left alone to prevent undesired endpoint reboots.

When using any control system; that system is communicating with our ZMP and not to any specific endpoint.

When sending RS232 commands to a decoder via the ZMP you must follow very specific syntax.

The ZeeVee command is: send <decoder_name> rs232 text

Here are examples on this. (Assume decoder name is *Dec1*)

Input command:  send Dec1 rs232 Hello
Received at Dec1: Hello (Note, no line feed or carriage return)

Input command:  send Dec1 rs232 Hello\n
Received at Dec1: Hello (with carriage return and line feed)

Input command:  send Dec1 rs232 Hello World
Received at Dec1: Nothing. You get an error. Bad syntax. You cannot have a space between Hello and World.

Input command send Dec1 rs232 Hello_World
Received at Dec1: Hello_World (Note, no line feed or carriage return)

Input command send Dec1 rs232 “Hello World”
Received at Dec1: Hello World (Note, no line feed or carriage return)

Input command send Dec1 rs232 “Hello World”\n
Received at Dec1: Nothing. You get an error. Bad syntax. Token \n is invalid.

You need to contain the line feed and carriage return symbols inside the quotes in this case.

Input command send Dec1 rs232 "Hello World\n"
Received at Dec1: Hello World (with carriage return and line feed)

Text can also be Hexadecimal Code as shown below:

Input command:
send Dec1 rs232 \x48\x65\x6c\x6f\x20\x57\x6f\x72\x6c\x64\x0A\x0D
Received at Dec1: Hello World (with carriage return and line feed)

The ZyPer Management Platform also has the ability to receive RS232 communications that were input into a ZyPer endpoint. To view any such RS232 string, you use the “show responses” command.

Example:
Zyper$ show responses DEC1 rs232 since 0
device(d8:80:39:59:bf:57);
  device.rs232Response.0; string="Have a great day!\x0D"
  device.rs232Response.1; string="\x0A"
lastChangeId(2);
Success
**Important Crestron Note**

When using Crestron as the control system, you need to append an extra `\` symbol before the Carriage return symbol. Otherwise carriage return does not work.

Example using Crestron to turn on/off LG display.

```
LG TV
ON
send DecoderName rs232 \x6B\x61\x20\x30\x30\x20\x31\x0D
OFF
send DecoderName rs232 \x6B\x61\x20\x30\x30\x20\x30\x0D
```
Troubleshooting Tips

If a command issued from a 3rd party control system is not working, the first thing to do is confirm the command works when issued directly in the API. To do this you should Telnet or SSH into the API using a tool such as Putty.
Once the Telnet or SSH session is open, you can issue any API command to the ZyPer Management Platform manually. You can also use the HELP feature of the API to learn the correct API commands and syntax.

Once the command is working via Telnet directly to the ZMP, copy the exact syntax as needed into the 3rd party control system.

**Support**

Modules/Drivers for 3rd party control systems are provided as a courtesy to developers in an effort to reduce development time. They are provided “as-is” from ZeeVee with no additional support provided other than the accompanying documentation. See **Disclaimers** section at the beginning of this document.
